In the 2-D case the problem is easily solved in time O(n log n).In the general 3-D case the problem is quite hard to solve, and is not even discrete; we present a doubly exponential procedure for solving the discrete subproblem of determining the sequence of boundary edges through which the shortest path passes. Finally we consider a favorable special case of the 3-D shortest path problem, namely that of finding the shortest path between two points along the surface of a convex polyhedron, and solve it in time O(n log n). The problem of finding the shortest path between two points in Euclidean space bounded by a finite collection of polyhedral obstacles is a special case of the more general problem of planning optimal collision-free paths for a given robot system (here we treat the robot as a single moving point). In two dimensional space the problem is easy to solve, because the shortest path between two given points must be a polygonal line whose vertices are comers of the given polygonal obstacles, so that the problem can be immediately reduced to a discrete graph searching, and can be solved in time 0(n log n), where n is the number of obstacle comers. This two-dimensional problem has been considered by Lozano-Perez and Wesley [Lw], and later also by Lee and Preparata [Lp]. In some special cases, considerably more efficient algorithms exist.
